10116 Line Receiver

Triple Differential Line Receiver

FEATURES

- Typical propagation delay: 2.4ns
- Typical supply current ($-I_{EE}$): 17mA

DESCRIPTION

The 10116 is a Triple Differential Line Receiver with low-impedance emitter-follower complementary outputs.

Intended primarily to receive data from twisted-pair lines, this device is also suitable for minicomputers, testing and instrumentation. It can also be used as a sense amplifier for MOS RAMs as a MOS-to-ECL interface circuit; as a high-speed comparator and having an internal reference supply voltage (V_{BB}) output, it can operate as a Schmitt Trigger.

One input from any unused amplifier in a package must be tied to V_{BB} .

NOTES:

1. The specified limits represent the worst case values for the parameter. Since these worst case values normally occur at the supply voltage and temperature extremes, additional noise immunity can be achieved by decreasing the allowable operating condition ranges.
2. Conditions for testing shown in the tables are not necessarily worst case. For worst case testing guidelines, refer to DC Testing, Chapter 1, Section 3.
3. The specified limits shown in the DC Electrical Characteristics table can be met only after thermal equilibrium has been established. Thermal equilibrium is established by applying power for at least 2 minutes, while maintaining transverse airflow of 2.5 meters/sec (500 linear feet/min) over the device, mounted either in a test socket or on a printed circuit board. Test voltage values are given in the DC Operating Conditions table.
4. Refer to DC Test Circuit.
