The window discriminator compares an input voltage to a defined voltage window. The digital outputs show whether the input voltage is below, within or above this window.

The TCA 965 B window discriminator is especially suitable as a tracking or compensating controller with a dead band in control engineering and for the selection of DC voltages within a certain tolerance of the required setpoint value in measurement engineering. When it is used as a Schmitt trigger, switching frequencies up to a typical value of 50 kHz are possible.

**Functional Description**

Amplifier Amp 3 increases the voltage of the reference source  $R$  to  $V_{Stab} = 2 \times V_{REF}$ . The amplification factor can be altered by external wiring. With direct setting of the window, the input voltage appears on amplifier Amp 1 ( $V_8$ ), the upper edge voltage on comparator K2 ( $V_6$ ) and the lower edge voltage on comparator K1 ( $V_7$ ).

With indirect setting of the window, the input voltage appears on inputs  $V_6$  and  $V_7$ , while the center voltage is connected to amplifier A1 ( $V_8$ ).

The voltage applied to the input ( $V_9$ ) of amplifier Amp 2 is subtracted symmetrically from the output voltage of amplifier Amp 1 and added. The comparators switch with hysteresis. The logic gates have open-collector outputs.

If the inhibit input A or B is connected to ground, output A or B will always be high.
