

12-BIT, 21-MSPS, ULTRALOW-POWER CCD SIGNAL PROCESSOR

FEATURES

- 12-Bit, 21-MSPS, Analog-to-Digital Converter
- Low Power: 70 mW Minimum
Power-Down Mode: 4 mW
- Low Input-Referred Noise: 75-dB
SNR Typical at 0-dB Gain
- Novel Optical-Black (OB) Calibration
- Low-Aperture Delay
- Single 3-V Supply Operation
- DNL: $<\pm 0.5$ LSB and
INL: $<\pm 1.5$ LSB Typical at 0-dB Gain
- Programmable-Gain Range: 0 dB to 36 dB,
Gain Resolution of 0.05 dB/Step
- 48-Pin TQFP Package

APPLICATIONS

- Digital Still Camera
- Digital Video Camera

DESCRIPTION

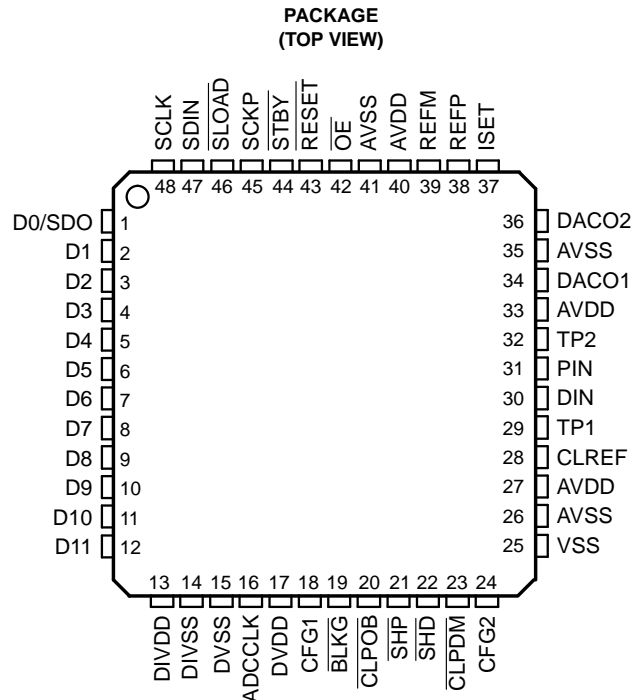

The VSP1221 is a highly-integrated mixed-signal IC used for signal conditioning and analog-to-digital conversion at the output of a CCD array. The IC has a correlated double sampler (CDS) and an analog programmable-gain amplifier (PGA) stage followed by an analog-to-digital converter (ADC) and a digital PGA stage. The CDS is used to sample the CCD signal and is followed by the analog PGA stage. The ADC is a 12-bit, 21-MSPS pipelined ADC. The digital PGA provides further amplification.

Additionally, there is an offset calibration loop for optical-black correction. The optical-black reference level is user-programmable. The chip also has two 8-bit digital-to-analog converters (DAC) for external analog settings.

The chip has a serial port for configuring internal control registers.

The VSP1221 is available in a 48-pin TQFP package and operates from a single 3-V power supply.

PIN ASSIGNMENTS

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

Terminal Functions

TERMINAL NAME	PIN	TYPE ⁽¹⁾	DESCRIPTION
D0 /SDO	1	DO	D0 = Bit 0 ADC output, least-significant bit (LSB) SDO = Serial data output (used for register read back)
D1	2	DO	Bit 1 ADC output
D2	3	DO	Bit 2 ADC output
D3	4	DO	Bit 3 ADC output
D4	5	DO	Bit 4 ADC output
D5	6	DO	Bit 5 ADC output
D6	7	DO	Bit 6 ADC output
D7	8	DO	Bit 7 ADC output
D8	9	DO	Bit 8 ADC output
D9	10	DO	Bit 9 ADC output
D10	11	DO	Bit 10 ADC output
D11	12	DO	Bit 11 ADC output, most-significant bit (MSB)
DIVDD	13	P	Power supply for digital I/O
DIVSS	14	P	Digital ground for digital I/O
DVSS	15	P	Digital ground
ADCCLK	16	DI	ADC clock
DVDD	17	P	Digital power supply
CFG1	18	DI	Configuration pin 1. Must be connected to GND
BLKG	19	DI	Blanking pulse: High = Normal operation Low = Digital output as programmed in the blanking register (see the <i>blanking register</i> section)
CLPOB	20	DI	Optical-black clamping pulse (default = active low)
SHP	21	DI	CDS reference sampling pulse (default = active low)
SHD	22	DI	CDS data sampling pulse (default = active low)
CLPDM	23	DI	Dummy clamping pulse (default = active low)
CFG2	24	DI	Configuration pin 2. Must be connected to GND
VSS	25	P	Substrate ground
AVSS	26, 35, 41	P	Analog ground
AVDD	27, 33, 40	P	Analog power supply
CLREF	28	AO	External decoupling for clamp voltage
TP1	29	AIO	Test point. Do not connect
DIN	30	AI	CCD signal input
PIN	31	AI	Input ground
TP2	32	AIO	Test point. Do not connect
DAC01	34	AO	General-purpose 8-bit DAC output voltage
DAC02	36	AO	General-purpose 8-bit DAC output voltage
ISET	37	AO	Internal bias-current setting
REFP	38	AO	External decoupling for internal positive reference
REFM	39	AO	External decoupling for internal negative reference
OE	42	DI	Output data enable: Low = Normal operation High = Digital output high impedance state
RESET	43	DI	Hardware reset (active low)
STBY	44	DI	Hardware power down (active low)

(1) P: Power Supply, AI: Analog input, AO: Analog output, AIO: Analog input/output, DI: Digital input, DO: Digital output

Terminal Functions (continued)

TERMINAL NAME	PIN	TYPE ⁽¹⁾	DESCRIPTION
SCKP	45	DI	SCKP - Serial clock polarity: High = Sample serial data on rising edge of serial clock (pin 48) Low = Sample serial data on falling edge of serial clock (pin 48)
SLOAD	46	DI	Serial data latch
SDIN	47	DI	Serial data input
SCLK	48	DI	Serial clock input

FUNCTIONAL BLOCK DIAGRAM

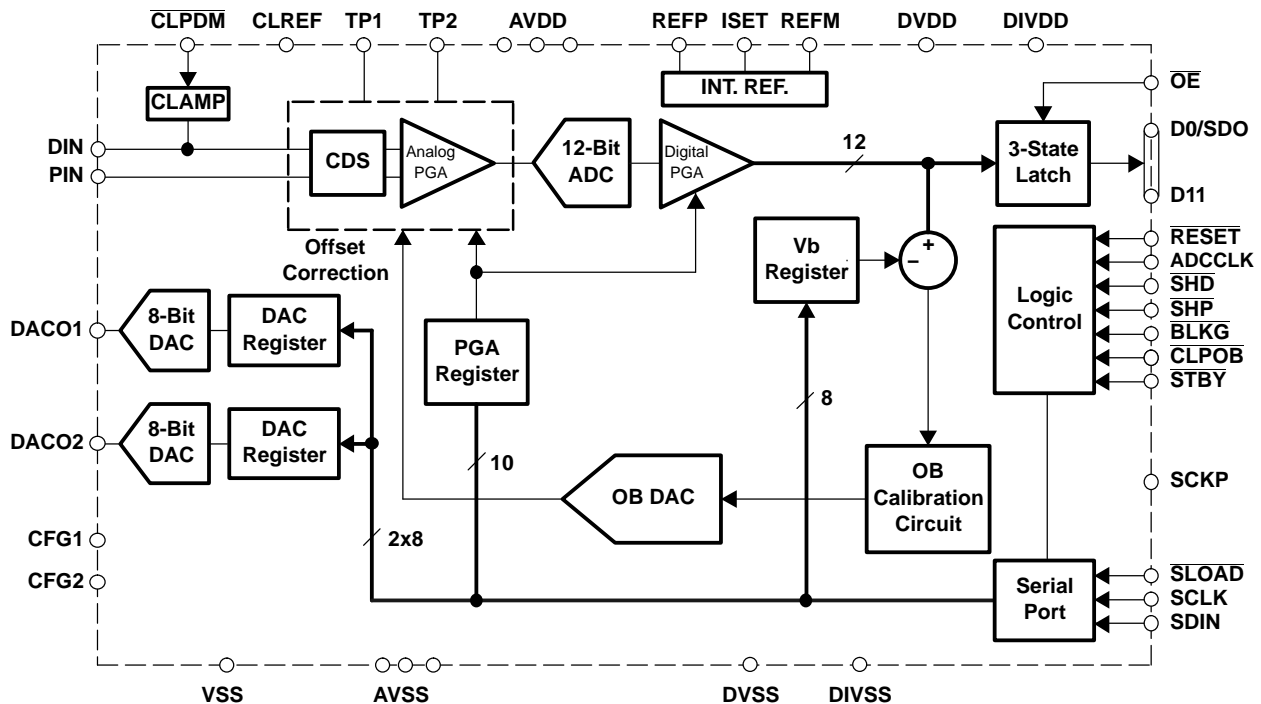

Figure 1. Internal Block Diagram for the VSP1221

ABSOLUTE MAXIMUM RATINGS⁽¹⁾

over operating free-air temperature range (unless otherwise noted)

	UNIT
Supply voltage, AV _{DD} , DV _{DD} , DIV _{DD}	-0.3 V to 6.5 V
Analog input voltage	-0.3 V to AV _{DD} + 0.3 V
Digital input voltage	-0.3 V to DV _{DD} + 0.3 V
Junction temperature, T _J	0°C to 150°C
Storage temperature, T _{stg}	-65°C to 150°C
Lead temperature, (10 sec)	260°C

(1) Stresses beyond those listed under „absolute maximum ratings“ may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under „recommended operating conditions“ is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

GENERAL SPECIFICATIONS

All typical specifications are at $T_A = 25^\circ\text{C}$, all power supply voltages = 3 V, and conversion rate = 21 MHz, unless otherwise stated. All maximum specifications are assured across operating temperature and voltage ranges.

PARAMETERS		TEST CONDITIONS	MIN	TYP	MAX	UNIT
POWER SUPPLY						
V_{DD}	Analog supply voltage		2.7	3	3.3	V
DV_{DD}	Digital supply voltage		2.7	3	3.3	
DIV_{DD}	Digital I/O supply voltage		1.8		3.3	
AV_{DD}	Operating current		20	24	29	mA
DV_{DD}			2	4	6	
DIV_{DD}			0.5	1	4	
Power dissipation		Normal mode	80	90	100	mW
		Power-down mode	1	2	4

SERIAL INTERFACE TIMING

Standard Functionality, SCKP (Pin 45) = High (Sample Data on Rising Edge of SCLK),
Operation = Write

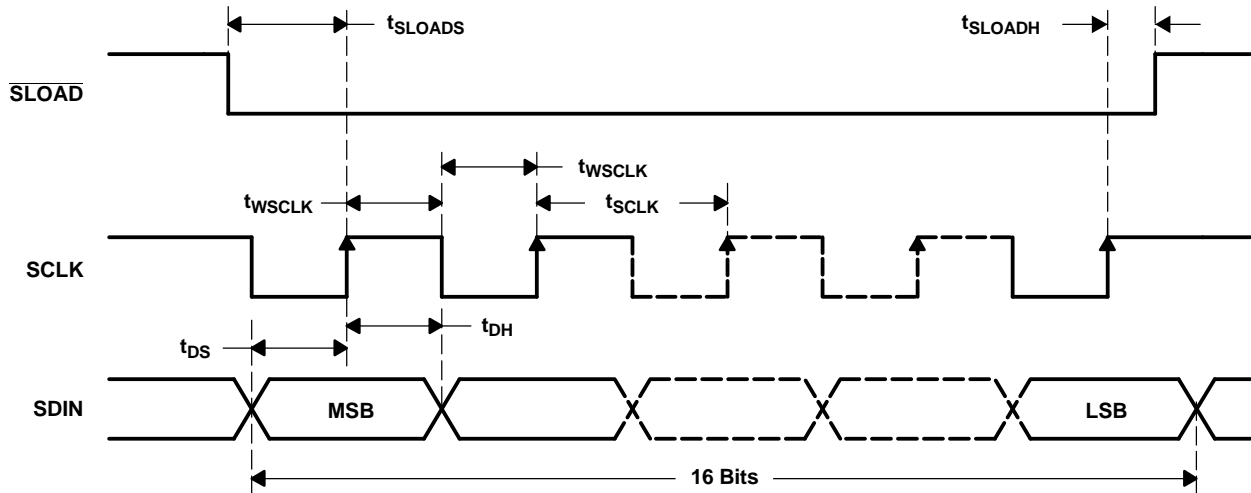

Figure 3. Serial Interface Timing for Write, SCKP = High

Standard Functionality, SCKP (Pin 45) = Low (Sample Data on Falling Edge of SCLK),
Operation = Write

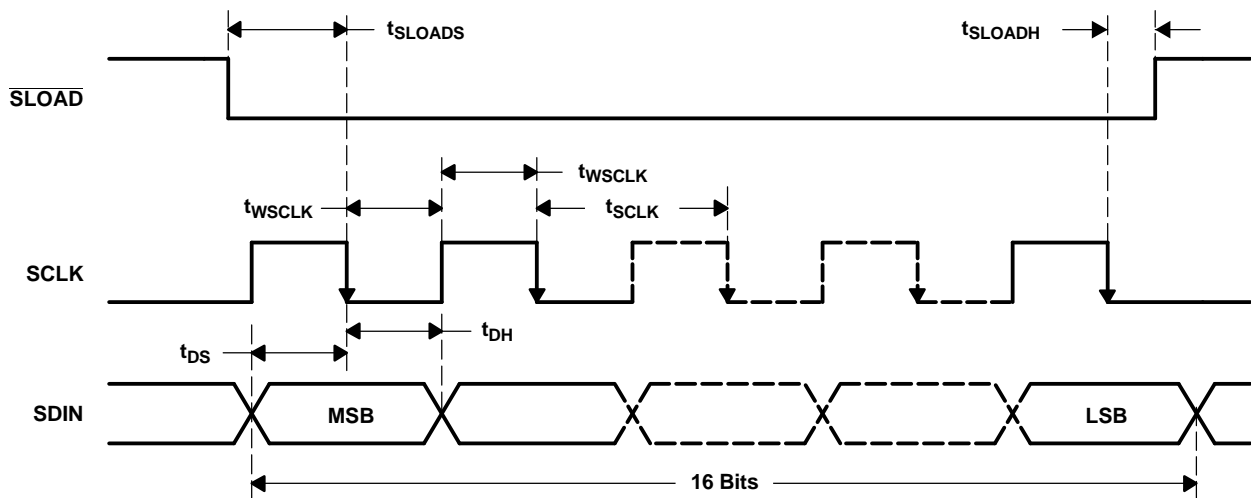

Figure 4. Serial Interface Timing for Write, SCKP = Low

SERIAL INTERFACE TIMING FOR WRITE, SCKP = LOW					
PARAMETERS		MIN	TYP	MAX	UNIT
t_{SCLK}	SCLK period	25			ns
t_{WSCLK}	SCLK high or low width	12.5			ns
t_{SLOADS}	\overline{SLOAD} to SCLK setup time	5			ns
t_{SLOADH}	SCLK to \overline{SLOAD} hold time	2			ns
t_{DS}	Data setup time	5			ns
t_{DH}	Data hold time	2			ns

Standard Functionality, SCKP (Pin 45) = High, Operation = Read

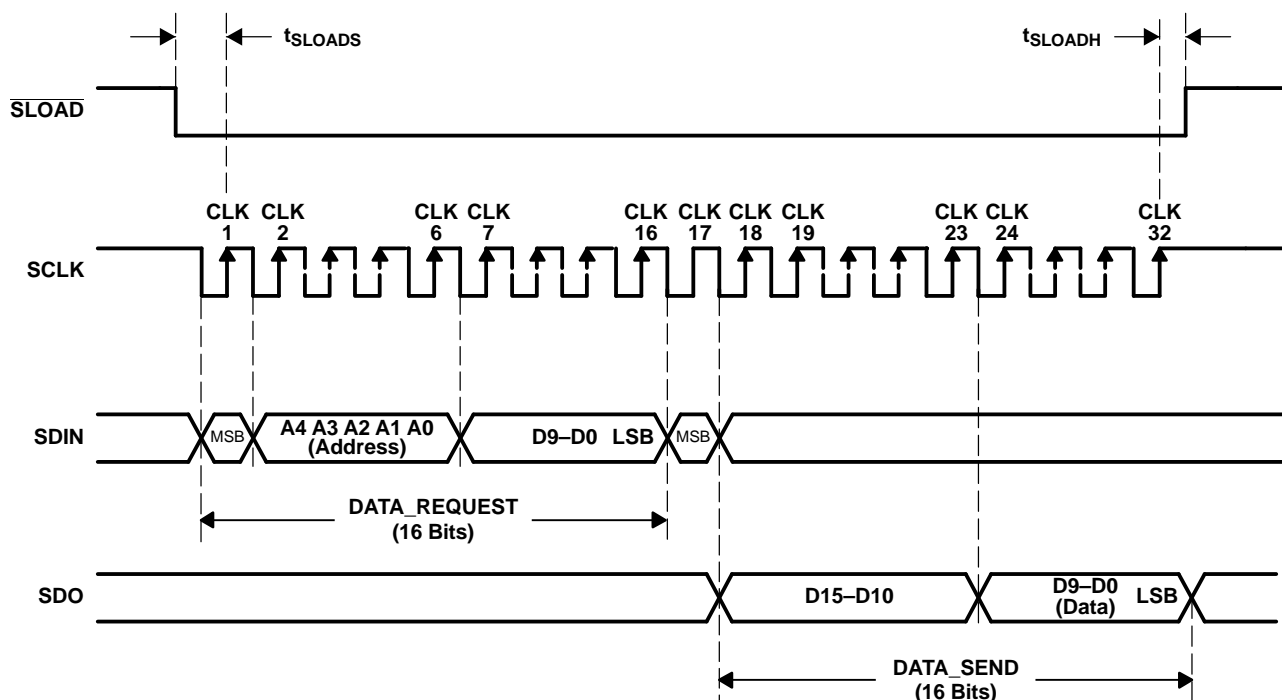

Figure 5. Serial Interface Timing for Read, SCKP = High

Device register values can be read back serially from the SDO pin (pin 1). For serial data read, user first sends a 16 bit DATA_REQUEST on the SDIN pin (pin 47). The format is as follows:

DATA_REQUEST on SDIN

SD15	SD14-SD10	SD9-SD0
1	Required register address	Don't Care

Although the length of DATA_REQUEST is 16 bits, the ten LSBs are don't cares. Also, note that SD15 ($\overline{RD}/\overline{WR}$) should be 1 for register read (see the *serial data format* section). The register address portion of DATA_REQUEST is decoded and the register data value (DATA_SEND) is available on the SDO pin at the rising edge of CLK18 (see Figure 5) if SLOAD is low at that time. If SLOAD is high at that time, then DATA_SEND is available when \overline{SLOAD} goes low again. The format of DATA_SEND is as follows:

DATA_SEND on SDO

SD15-SD10	SD9-SD0
Don't Care	Required register data

Although the length of DATA_SEND is 16 bits, the six MSBs are don't cares.

SDO Timing

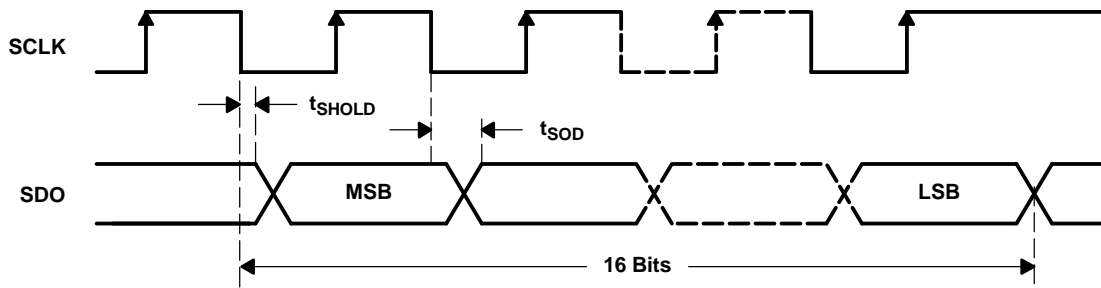

Figure 6. Serial Interface Timing Between SCLK and SDO

SERIAL INTERFACE TIMING BETWEEN SCLK AND SDO ⁽¹⁾					
PARAMETERS		MIN	TYP	MAX	UNIT
t_{SHOLD}	Data output hold time	5			ns
t_{SOD}	Data output delay			13	ns

(1) Data output transition occurs at the falling edge of SCLK; so data should be sampled at the rising edge of SCLK. Since the SDO pin is multiplexed with the D0 pin, \overline{OE} (pin 42) should be low.

Standard Functionality, SCKP (Pin 45) = Low, Operation = Read

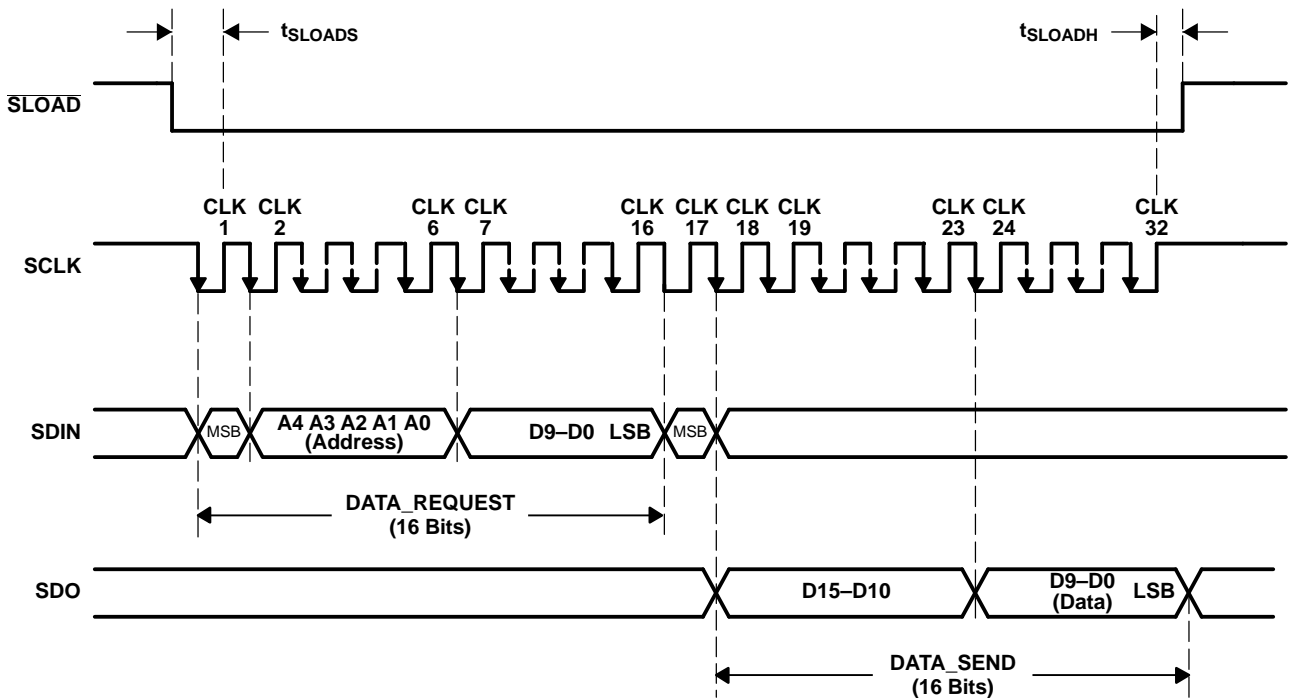

Figure 7. Serial Interface Timing for Read, SCKP = Low

The SDO timing is the same as before, except that data should be sampled at the falling edge of SCLK.

SERIAL DATA FORMAT

Standard Functionality

The serial data is always grouped in 16-bit blocks with the following format. Multiple 16-bit blocks can be send through the SDIN pin (pin 47) keeping $\overline{\text{SLOAD}}$ (pin 46) low.

SD15 MSB	SD14	SD13	SD12	SD11	SD10	SD9	SD8	SD7	SD6	SD5	SD4	SD3	SD2	SD1	SD0 LSB
$\text{RD}/\overline{\text{WR}}^{(1)}$	A4	A3	A2	A1	A0	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
Register Address						Register Data									

(1) $\text{RD}/\overline{\text{WR}} = 0$, Write into registers, $\text{RD}/\overline{\text{WR}} = 1$, Read from registers

REGISTER DESCRIPTION ⁽²⁾

REGISTER ADDRESS					REGISTER NAME	REGISTER FUNCTION

PRINCIPLES OF OPERATION

INTRODUCTION

The principle functions of the VSP1221 are described below. The sections discussed are:

- CDS
- ADC
- PGA
- Voltage and current reference
- Serial interface
- Timing
 - $\overline{\text{SHP}}$, $\overline{\text{SHD}}$, AND ADCCLK
 - $\overline{\text{CLPDM}}$
 - $\overline{\text{BLKG}}$
 - $\overline{\text{CLPOB}}$
 - $\overline{\text{OE}}$
 - $\overline{\text{RESET}}$
- Optical-black calibration
- Standby mode
- General-purpose DAC

Before describing the individual blocks, a simplified block diagram of the VSP1221 is shown in Figure 8.

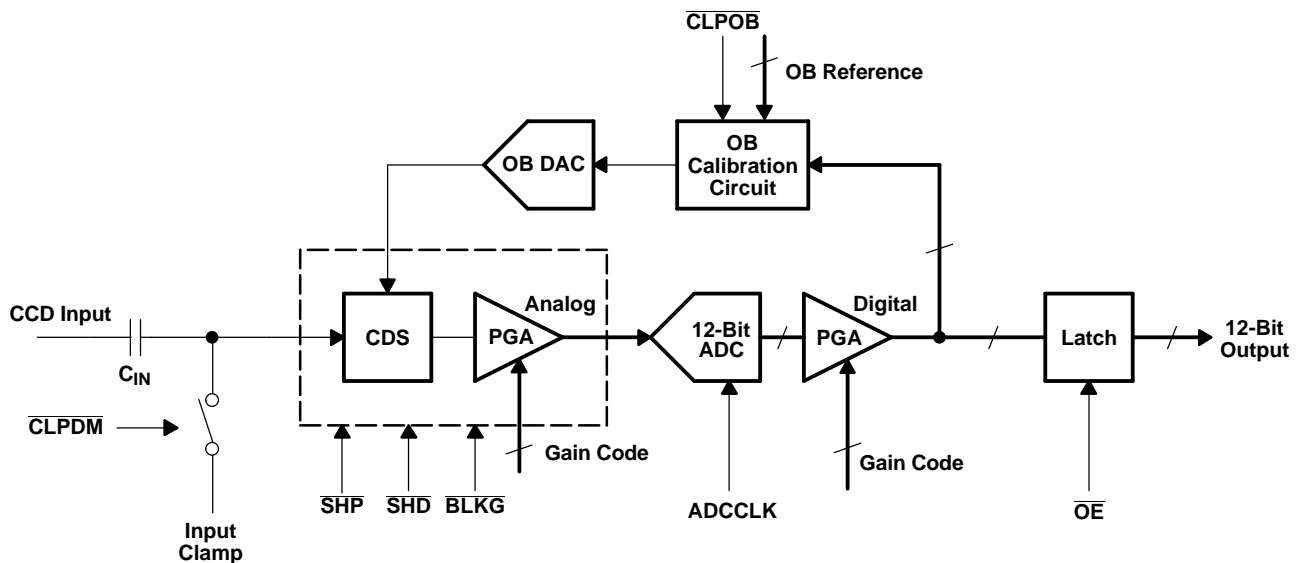

Figure 8. Simplified Block Diagram of the VSP1221

CDS

The output signal from the CCD is fed to the correlated double sampler (CDS) through off-chip coupling capacitor C_{in} (a 0.22- μF capacitor is recommended for C_{in}). The CCD signal is sampled twice during one pixel period: at the reference level ($\overline{\text{SHP}}$) and at the data level ($\overline{\text{SHD}}$). Subtracting these two samples extracts the pixel value and reduces the reset noise and other low-frequency noises that are present at the output of the CCD signal.

ADC

The output analog signal from the analog PGA stage is passed to the 12-bit analog-to-digital converter (ADC). The ADC employs a three-stage pipelined architecture to achieve high-throughput and low-power consumption. Fully-differential implementation and digital-error correction ensures 12-bit resolution.

PRINCIPLES OF OPERATION (continued)

PGA

VSP1221 has a programmable gain amplifier (PGA) which is composed of analog and digital stages. The total gain range is 0 dB-36 dB in 0.05-dB steps. The gain can be adjusted by programming the PGA register through the serial port, see the *programmable gain amplifier (PGA) register* section.

VOLTAGE REFERENCE

All the reference voltages and the bias currents used by the device are created by an internal bandgap circuit. Connecting an external 100-k Ω resistor from ISET (pin 37) to ground provides the bias current. The voltage at the ISET pin is 1 V and the reference current is 10 μ A (1 V/100 k Ω). The reference voltages for the ADC are REFP (2.05 V) and REFM (0.75 V). They are available on pins 38 and 39, respectively. The full-scale range of the ADC is twice the difference between REFP and REFM. Pins REFP and REFM should be heavily decoupled with appropriate capacitors (1 μ F recommended).

SERIAL INTERFACE

Standard Functionality

A simple three-wire (SCLK, SDIN, and $\overline{\text{SLOAD}}$) serial interface is provided to allow writing/reading the internal registers of the VSP1221. The serial data SDIN (pin 47) is 16 bits long. The MSB (most significant bit) is set to 0 for writing to and to 1 for reading from the internal registers. Following this, there are five address bits for accessing and ten data bits for writing to the particular registers. During a read operation, data from the particular register is available on SDO (pin 1). To enable serial read/write, $\overline{\text{SLOAD}}$ (pin 46) should be pulled low. Sending blocks of 16-bit data to SDIN can program multiple registers. The polarity of the serial clock (SCLK, pin 48) can be controlled by SCKP (pin 45). For serial interface timing see the *serial data format* section; for serial data format and description of the internal registers see the *register description* section.

TIMING

A description of the different timing signals of the VSP1221 follows. The timing diagram in the *sample and conversion timing* section has additional information. Note that the polarity of $\overline{\text{SHP}}/\overline{\text{SHD}}$, ADCCLK, $\overline{\text{CLPDM}}$, BLKG, and CLPOB can be programmed to be active low or active high (see the *signal polarity register* section). The timing diagram in the *timing specifications* section is based on active-low polarity.

$\overline{\text{SHP}}$, $\overline{\text{SHD}}$, and ADCCLK

$\overline{\text{SHP}}/\overline{\text{SHD}}$ are used for correlated double sampling of the CCD signal. Sample reference ($\overline{\text{SHP}}$) is used to sample the reference level of the CCD signal, and sample data ($\overline{\text{SHD}}$) is used to sample the data level. The ADC clock (ADCCLK) is used to latch the output of the ADC to the external pins. $\overline{\text{SHP}}$, $\overline{\text{SHD}}$, and ADCCLK are used to generate internal timing signals using the on-chip timing generator for proper synchronization of different blocks. $\overline{\text{SHP}}$, $\overline{\text{SHD}}$, and ADCCLK can be internally delayed by programming the timing registers through the serial port (see the *timing register 1* and *timing register 2* sections).

The following is recommended to get the best performance:

SHP and SHD must first be aligned based on the CCD signal and timing shown in Figure 2 (t_{DSHP} and t_{DSDH}). It is observed that if output data switches at the instant of sampling (t_{DSHP}), the device noise performance degrades. The data switches a few ns after the rising edge of ADCCLK (t_{OD}). To improve performance, ADCCLK can be varied within the $t_{\text{ADC_SHD}}$ range.

$\overline{\text{CLPDM}}$

The CCD signal is capacitively coupled to the VSP1221 because the dc level of the CCD signal is usually too high and might damage the chip. The purpose of the $\overline{\text{CLPDM}}$ signal is to clamp the ac-coupling capacitor C_{in} to establish the proper dc bias for the CDS. The dc bias for the CDS is set to the clamp voltage, which is around 800 mV below the supply voltage. The clamp voltage can be decoupled with an external capacitor at CLREF (pin 28). This helps in charging the ac-coupling capacitor C_{in} faster, since the charge will be provided by the decoupling capacitor. The recommended value for the decoupling capacitor is 1 μ F. The dummy pixel clamp ($\overline{\text{CLPDM}}$) signal is usually available during the dummy pixels of the CCD and is applied at the line rate of the CCD sensor.

PRINCIPLES OF OPERATION (continued)

$\overline{\text{BLKG}}$

Some CCDs have large transient output signals during blanking intervals. Such signals might drive the VSP1221 into saturation and can cause long recovery times. To prevent this, the VSP1221 has an input-blanking function which disconnects the CCD input from the CDS when it receives the blanking ($\overline{\text{BLKG}}$) signal. Additionally, the output from the VSP1221 during blanking will be equal to the value programmed in the blanking register. The blanking level can be adjusted by programming the blanking register through the serial port (see the *blanking register* section).

$\overline{\text{CLPOB}}$

The optical-black clamp ($\overline{\text{CLPOB}}$) pulse is used for optical-black calibration (explained in the *optical-black calibration* section). The $\overline{\text{CLPOB}}$ pulse is given to the device during optical-black pixels of the CCD.

$\overline{\text{OE}}$

Output enable ($\overline{\text{OE}}$) is used to latch the output data to the output pins. When $\overline{\text{OE}}$ is low, data is latched to the output pins (D0-D11); when it is high, the output is 3-state.

$\overline{\text{RESET}}$

When the reset ($\overline{\text{RESET}}$) signal is pulled low (hardware reset), all the internal registers are reset to their default values. In addition, the device also has a software-reset option that allows setting the RTSY bit in the control register through the serial port (see the *control register* section). See the *control register* section for the default values of the internal registers. In addition to resetting the registers, hardware reset also resets the output of the OB DAC to zero. However, to exactly reset the OB DAC to zero, $\overline{\text{RESET}}$ must be kept low for approximately 600 ns.

OPTICAL-BLACK CALIBRATION

Optical-black calibration (OB) is used to clamp the CCD *black* level to the user-defined OB reference level. In CCDs, thermally generated electrons produce a significant amount of charge even at room temperature. So, even in the absence of light (*black* level), thermal electrons generate a considerable amount of current in CCDs. Thus, the CCD black level carries a residual signal, also known as the CCD offset, which is typically in the order of 50 mV. This residual signal reduces the effective dynamic range of the CCD input, resulting in a degradation of image quality. An offset voltage must be subtracted from the CCD black level so that the difference between the CCD black level and the offset voltage is equal to the reference OB level programmed by the user. The reference OB level is much lower than the CCD black level, so that the effective dynamic range of the CCD input increases and the image quality improves. The offset voltage has to be determined based on the CCD black level. There are certain CCD pixels which are not exposed to light (optical-black pixels) and the CCD signal corresponding to these pixels represent the CCD black level. Thus, the offset voltage is determined during the optical-black pixels, and the offset voltage is kept constant and is subtracted from the CCD input to cancel the CCD offset during normal image pixels.

OB calibration in the VSP1221 is done in a closed feedback loop. The difference between the CCD black level and the offset voltage is compared with the user-defined OB reference level at the output of the digital PGA stage. The error is fed to an OB calibration circuit which generates a step proportional to the error and a sign based on the sign of the error. The step and the sign are then given to the OB DAC, which generates an analog voltage that updates the offset voltage at the input of the CDS. If the error is positive, the offset voltage is increased; if the error is negative, the offset voltage is decreased. This continues in a closed feedback loop until the difference between the CCD black level and the offset voltage converges to the OB reference level. The OB calibration circuit has been designed so that a 100-mV CCD black level converges to zero-reference OB level within 500-750 pixel clocks. Convergence time increases with an increase in gain. Convergence is faster if the CCD black level is smaller than 100 mV. A plot of the convergence time as a function of the PGA gain is shown in the *performance plots* section. Since the feedback loop includes the CDS, the PGA, and the ADC, it also cancels any offset introduced by these blocks. The OB reference level can be adjusted by programming the OB register through the serial port (see the *OB register* section).

PRINCIPLES OF OPERATION (continued)

STANDBY (POWER-DOWN MODE)

To save power, the VSP1221 can be put into standby mode (power-down mode) both through hardware and software. Pulling the $\overline{\text{STBY}}$ signal low puts the device into standby mode (hardware power-down). In this mode, the reference is pulled down, all the functional blocks are disabled, the output is *all zero*, and the power dissipation is zero. The power-up time is of the order of 10 ms. Software power down can be exercised by resetting the STBYZ bit in the control register through the serial port (see the *control register* section). This is similar to hardware power down, except that the reference is not pulled down. Hence, the power dissipation is around 4 mW and the power-up time is of the order of 10 μs . The user can still program all the internal registers during both hardware and software power down.

GENERAL PURPOSE DAC

The VSP1221 has two 8-bit general-purpose digital-to-analog converters (DACs) that can be used for external analog settings. The output voltage of each DAC can be independently set and has a range of 0 V to the supply voltage with eight-bit resolution. The digital input to the DACs can be set by programming the User DAC1 and User DAC2 registers through the serial port (see the *User DAC1 register* and *User DAC2 register* sections). When not used in the system, the DACs can be put in standby mode by programming the above-mentioned registers. The DACs are, by default, in standby mode. The average power consumed by each DAC is approximately 1 mW.

APPLICATION INFORMATION

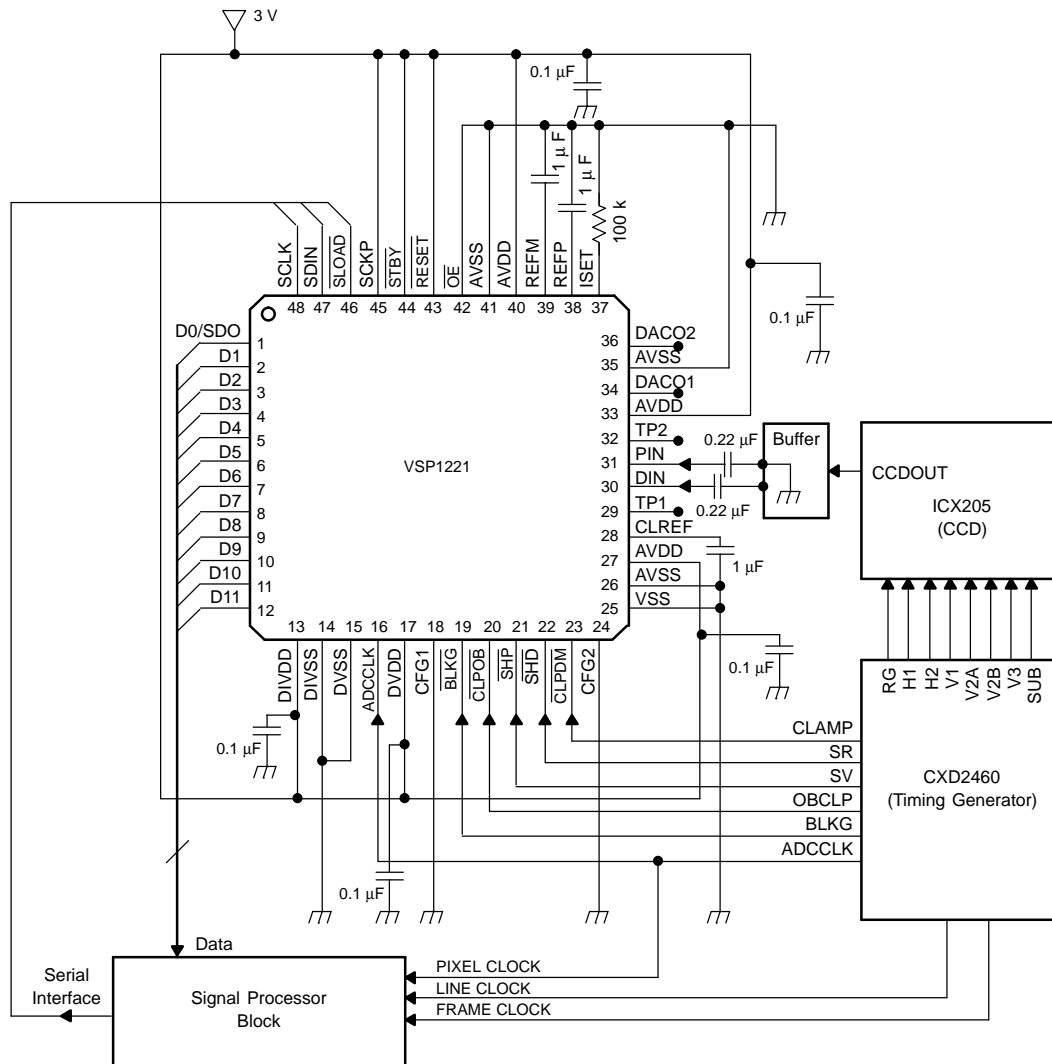

Figure 9. Application Diagram of the VSP1221

NOTE:

The application circuits shown are typical examples of the operation of the devices. Texas Instruments cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third-party patents and other rights due to the same.

CCD INPUT

The CCD output may need an off-chip external buffer in order to drive the input capacitive load of the VSP1221. The buffer output is applied to DIN (pin 30) through an ac-coupling capacitor. It is advisable to connect PIN (pin 31) to the buffer ground through a similar ac-coupling capacitor for the following reason: since the input stage of the VSP1221 is differential, the input to the CDS is the voltage difference between DIN and PIN. Hence, if the noise path for DIN and PIN are similar, the noise can be effectively cancelled. This is not the case if the noise paths are different. However, PIN can also be connected directly to ground. In this case, bit SD8 (CLAMP PIN) of the control register should be 1 (see the *control register* section). If PIN is connected to an ac-coupling capacitor, it is recommended to set bit SD8 (CLAMP PIN) of the control register to 0 so that the ac-coupling capacitor is charged to a fixed clamp voltage. The recommended value for the ac coupling capacitor is 0.22 μF.

APPLICATION INFORMATION (continued)

REFERENCE DECOUPLING

Pins REFP (pin 38) and REFM (pin 39) should be connected to ground by means of decoupling capacitors. A 1- μ F ceramic capacitor is recommended for reference decoupling. For better high-frequency decoupling, 0.1 μ F ceramic capacitors may be used in parallel. The decoupling capacitors should be placed as close as possible to the reference pins.

CLAMP DECOUPLING

To decouple the clamp voltage, a 1- μ F ceramic capacitor may be connected to CLREF (pin 28). See the *CLPDM* section for further details.

INTERNAL BIAS CURRENT SETTING

To set the internal bias current, ISET (pin 37) should be connected to ground through a 100-k Ω resistor. *However, no capacitor should be connected to the ISET pin.*

POWER SUPPLY, GROUNDING, AND DEVICE DECOUPLING

The VSP1221 has several power-supply pins. Each major internal analog block has a dedicated AVDD supply pin (pins 27, 33, and 40). The DVDD supply pin (pin 17) powers all internal digital circuitry. Both AVDD and DVDD work with 3-V power supplies. DIVDD and DIGND (pins 13 and 14) supply power to the output digital driver (D0-D11). DIVDD is independent of DVDD and can be operated from 1.8 V to 3.3 V. This allows the outputs to interface with digital ASICs requiring different supply voltages

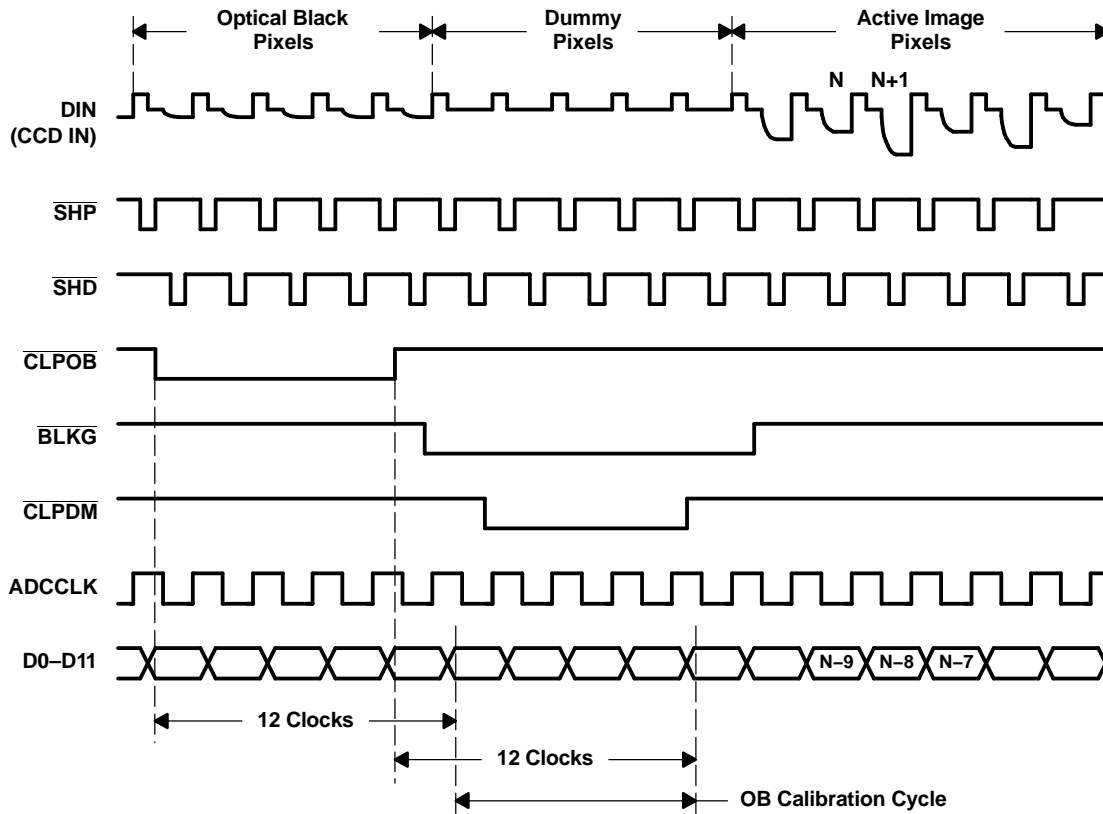

General design practices should apply to the PCB to limit high-frequency transients and noise that are fed back into the supply lines. This requires adequate bypassing of the supply pins. In the case of power supply decoupling, 0.1- μ F ceramic capacitors are sufficient to keep the impedance low over a wide frequency range. Since their effectiveness depends largely on the proximity to the individual supply pin, all decoupling capacitors should be placed as close as possible to the supply pins.

To reduce high-frequency and noise coupling, it is highly recommended to short the digital and analog grounds immediately outside the package. This can be accomplished by running a low-impedance line under the package between pins DVSS and AVSS.

DATA OUTPUT

It is recommended to keep the capacitive loading on the output data lines as low as possible (typically less than 15 pF). Larger capacitive loads demand higher charging-current surges, which can feed back into the analog portion of the VSP1221 and affect its performance. If the data lines are long, it is advisable to use external buffers or latches, which also provides the added benefit of isolating the VSP1221 from any digital noise that may couple back. In addition, resistors in series with each data line helps in minimizing the surge current. Typical resistor values are 40-50 Ω .

APPLICATION INFORMATION (continued)

- OB Calibration latency is 12 clocks. So, OB update starts 12 clocks after \overline{CLPOB} is pulled low and stops 12 clocks after \overline{CLPOB} is pulled high.
- If active image pixels are located immediately after \overline{CLPOB} goes high, the OB update will affect the adjacent 12 pixels.
- The device clocks are stopped during \overline{BLKG} and \overline{CLPDM} . Therefore, if these signals appear immediately after \overline{CLPOB} goes high, the OB calibration update for the subsequent 12 clocks will stop. So, its recommended to delay \overline{BLKG} and \overline{CLPDM} by at least 12 pixels after \overline{CLPOB} goes high.

PACKAGING INFORMATION

Orderable Device	Status ⁽¹⁾	Package Type	Package Drawing	Pins	Package Qty	Eco Plan ⁽²⁾	Lead/Ball Finish	MSL Peak Temp ⁽³⁾
VSP1221PFB	NRND	TQFP	PFB	48	250	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR
VSP1221PFBG4	NRND	TQFP	PFB	48	250	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBsolete: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

- NOTES:
- A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Publication IPC-7351 is recommended for alternate designs.
 - D. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC-7525.
 - E. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
